X-ray crystallography is a technique used for determining the atomic and molecular structure of a crystal, in which the crystalline structure causes a beam of incident X-rays to diffract into many specific directions. By measuring the angles and intensities of these diffracted beams, a crystallographer can produce a three-dimensional picture of the density of electrons within the crystal.

X-rays make up X-radiation, a form of electromagnetic radiation. Most X-rays have a wavelength ranging from 0.01 to 10 nanometers, corresponding to frequencies in the range 30 petahertz to 30 exahertz ( $3\text{Å}—10^{16}$  Hz to  $3\text{Å}—10^{19}$  Hz) and energies in the range 100 eV to 100 keV. X-ray wavelengths are shorter than those of UV rays and typically longer than those of gamma rays.

An Introduction to X-ray Powder Diffraction Analysis. When a beam of X-rays illuminates a single crystal, many diffraction spots are generated. The positions of the spots are determined by the size and shape of the unit cell and the symmetry.

X-RAY FLUORESCENCE (XRF) When a primary x-ray excitation source from an x-ray tube or a radioactive source strikes a sample, the x-ray can either be absorbed by the atom or scattered through the material.

Many of the drugs used to treat breast cancer today are probable or known cancer-causing agents.

Tamoxifen, for instance, is classified by the World Health Organization as a "human carcinogen," but recent news headlines praised extended use of this drug for "saving lives."
